CHAPTER 1

INTRODUCTION

1.1 INTRODUCTION

Conversational Artificial Intelligence (AI) has become an essential component of modern digital systems, enabling machines to understand and respond to human language in a natural and interactive manner. Most AI-driven conversational platforms today rely heavily on cloud-based Large Language Models (LLMs) such as GPT, BERT, and LLaMA, which require continuous internet access, high computational power, and external server dependencies to function efficiently. While these systems are powerful, they introduce significant challenges related to privacy, security, cost, and dependency on external networks.

Traditional online AI systems send user data to cloud servers for processing, creating security vulnerabilities, especially in sensitive fields such as cyber security, defense networks, healthcare, and educational institutions. Furthermore, internet connectivity issues, latency, subscription costs, and remote server failures make cloud-based conversational systems unreliable in restricted or offline environments.

To address these limitations, this project introduces a **Standalone Conversational AI System (Internet-Free)** — a self-contained offline AI model capable of performing natural language understanding, text processing, and response generation without the need for cloud-based APIs or internet connectivity. The system uses **Dlib-based text embeddings**, a **local vector database**, and **offline retrieval-based generation**, ensuring complete data privacy and reliable performance even in air-gapped environments.

This offline AI model allows users to interact with a chatbot that generates accurate and context-aware responses using only locally stored data and algorithms. The core architecture eliminates external dependencies, promotes self-sovereign AI usage, and ensures users maintain full control over their data and the entire conversational process.

The system's design focuses on simplicity, accuracy, efficiency, and local storage-based intelligence. It is built especially for:

- cyber security labs

- remote regions with low or no internet
- private research environments
- secure organizations
- educational use cases
- personal offline assistants

This project demonstrates how conversational AI technologies can be democratized and deployed offline using lightweight computing resources. It proves that intelligent human–machine interaction is possible even without cloud infrastructure or large-scale online models.

1.2 OBJECTIVE

The primary objective of the **Standalone Conversational AI System (Internet-Free)** is to design and implement a fully offline conversational model that:

- **Removes cloud dependency:**
  Ensures all processing happens locally on the user's device without internet access.
- **Protects user privacy and data security:**
  No information is sent to external servers, making it suitable for secure environments.
- **Provides reliable offline AI responses:**
  Uses Dlib embeddings and a local vector store to generate meaningful responses.
- **Reduces operational cost:**
  No API usage charges, no server payments, and no network maintenance.
- **Improves accessibility:**
  Works in remote areas, rural regions, and environments with unstable or no internet access.

- **Demonstrates feasibility of offline AI:**
  Shows that conversational AI can run efficiently even on low-end hardware.

- **Implements efficient retrieval-based AI:**
  Uses vector similarity search to retrieve best-matched responses with low computing power.

- **Supports customization:**
  Allows users to extend the knowledge base by adding their own text data locally.

By implementing these objectives, the system provides an intelligent, secure, and reliable conversational agent that can be deployed anywhere without internet connectivity.

CHAPTER 2

LITERATURE REVIEW

2.1 Existing Survey

The development of offline conversational AI systems is inspired by a wide range of research studies in natural language processing, vector embedding models, and retrieval-based architectures. Several research works have explored methods for building intelligent chatbots using different machine learning techniques. The following literature provides insights into the foundations and evolution of offline conversational systems:

1. Dlib Embedding Architecture (Davis E. King, 2009)

Dlib is a widely used machine learning toolkit offering highly efficient numerical and vector-processing algorithms. Although originally designed for computer vision, Dlib's deep-learning-based embedding functions have been adapted for text vectorization and similarity matching. Studies show that Dlib's lightweight architecture is suitable for offline embedding generation on low-resource hardware, making it ideal for standalone AI applications.

2. Retrieval-Based Conversational Models (J. Weston, Facebook AI Research)

Retrieval-based chatbots store a knowledge base of pre-defined responses and use semantic similarity to find the best match. Research highlights that these systems:

- do not require large neural networks
- can run fully offline
- are efficient for small-to-medium datasets
- provide consistent, rule-based responses

This approach forms the foundation of the proposed offline conversational system.

3. Local Vector Database (FAISS, Annoy, HNSW)

Studies on vector databases developed by Facebook AI (FAISS), Spotify (Annoy), and HNSWlib demonstrate the efficiency of local similarity searches. These systems show that embeddings stored locally can be searched rapidly without cloud computing.

Their findings support the possibility of:

- high-speed vector search

- low-latency retrieval
- offline indexing

4. Privacy-Preserving AI (MIT, 2021)

Research on privacy-focused AI emphasizes the risks of sending user data to cloud servers. Many studies conclude that:

- Internet-based AI exposes sensitive information
- Offline AI ensures complete data confidentiality
- Edge computing and on-device models enhance trust

5. RASA Open-Source Conversational Framework (2019)

RASA introduced an offline NLU (Natural Language Understanding) engine that runs without cloud APIs. However, it still relies on larger ML pipelines and training data. Comparisons show that RASA is powerful but not optimized for extremely low-compute devices.

This project improves upon RASA by:

- eliminating training requirements
- using static embeddings
- implementing a lightweight vector engine

6. Offline NLP Models & On-Device AI (Google Edge TPU)

Research in on-device AI shows that NLP models can run efficiently on mobile hardware using optimized representations. Many studies highlight the advantages of:

- compact embedding models
- low-power inference
- offline language processing.

7. Retrieval-Augmented Generation (RAG) Techniques

Recent research in conversational AI uses RAG pipelines where:

- A query is embedded
- The system retrieves relevant chunks from local storage
- The response is generated using the retrieved information

CHAPTER 3

SYSTEM ANALYSIS

3.1 Existing System

The existing conversational AI systems available today heavily rely on cloud-based infrastructures, external APIs, and internet connectivity. Models such as ChatGPT, Dialogflow, IBM Watson Assistant, and Amazon Lex depend on remote servers to perform language modeling, training, and inference.

These cloud-driven systems work efficiently but come with several limitations. They require continuous internet access, subscription charges, high latency during network congestion, and expose user data to third-party servers. For organizations dealing with sensitive, private, or confidential information, these platforms are not suitable.

The existing system follows a centralized architecture where:

- The user sends a query
- The query is transmitted to a cloud server
- The model generates a response on the server
- The response is returned to the user's device

While effective, this model completely depends on external systems and cannot function without network connectivity

3.1.1 Drawbacks

Major Drawbacks of Offline Conversational AI Systems

1.Limited Knowledge Updates

Offline models cannot access the internet

Knowledge becomes outdated unless manually retrained or updated.

No real-time information, news, weather, financial data, or updated fact.

2. Higher Storage & Hardware Requirements

- Large AI models require gigabytes of storage and strong CPU/GPU resources.
- Many devices (mobiles, embedded systems) cannot run big models efficiently.

3. Reduced Accuracy & Capabilities

- Fewer capabilities (e.g., no real-time translation of emerging terms, smaller vocabularies).
- Offline models often must be smaller → less accurate, less fluent, weaker reasoning .

4. Manual Maintenance Burden

You must manage:

- Fine-tuning
- Security patches
- Bug fixes
- No automatic cloud updates.

5. No Cloud-Level Computation

Cannot perform heavy tasks like:

- Large document analysis
- Advanced vision-processing
- Real-time speech recognition at cloud accuracy

- Limited by local hardware.

6. Poor Personalization Across Devices

- Local data stays on one device → not synced.
- User personalization cannot follow across multiple devices unless you manually configure it.

7. Scalability Issues (for businesses)

- Each device needs its own copy of the model.
- Hard to scale to many users.
- Local servers need expensive GPUs if many people interact simultaneously.

8. Security & Compliance Challenges

- If the local machine is compromised, the AI system and user data can be accessed.
- Requires your own encryption, logging, and compliance setup (GDPR, HIPAA, etc.).

9. Limited Integration with Online Services

Cannot directly fetch:

- Emails
- Cloud files
- APIs
- Databases
- Must build custom offline interfaces.

10. Lack of Real-Time Collaboration Features

- No multiplayer or multi-user AI tools.

3.2 Proposed System

The proposed project presents a **Standalone Conversational AI System (Internet-Free)** that operates fully offline without relying on cloud servers. It uses **Dlib-based text embeddings**, a **local vector database**, and **local response retrieval**, ensuring complete independence from internet connectivity.

The system follows a decentralized, self-contained approach where:

- All data is stored locally
- All processing occurs on the user's device
- No external data sharing or communication occurs
- The response is generated from offline resources

This makes the system extremely secure, lightweight, and reliable.

Key Features of Proposed System

- Fully offline operation
- Complete user data privacy
- Low latency due to local computation
- No subscription charges or API limits
- Suitable for restricted networks
- Easy to install and deploy
- Extendable knowledge base loading

3.2.1 Advantages

1. 100% Offline Functionality

The model works without any internet connection.

2. High Data Privacy

All user queries stay inside the system.

No external servers are used, ensuring maximum security.

3. Fast Response Time

Local vector search enables immediate retrieval.

4. Cost-Free Operation

No need to pay for:

- API tokens
- subscription fees
- cloud computing
-

5. Reliability

Works in rural areas, offline labs, and secure cyber environments.

7. Customizable Knowledge Base

Users can add their own documents or text to create a personalized offline assistant.

CHAPTER 4

SOFTWARE SPECIFICATION

4.1 Hardware Requirements

To achieve optimal performance and ensure smooth offline conversational processing, the following hardware configuration is recommended:

Minimum Requirements

- **Processor:**
  Dual-core CPU (Intel/AMD)
  Capable of running Python-based applications and Dlib libraries.
- **RAM:**
  4 GB
  Sufficient for small-to-medium embedding datasets.
- **Storage:**
  1 GB free disk space
  Needed for storing embeddings, vector files, knowledge base, and logs.
- **Graphics:**
  No dedicated GPU required.
  The system uses CPU-optimized embedding operations.

Recommended Requirements

- **Processor:**
  Intel i5 / AMD Ryzen 5 or higher
  Ensures faster vector search and preprocessing.
- **RAM:**
  8 GB or above
  Allows running larger knowledge bases smoothly.
- **Storage:**
  2–4 GB free space
  Suitable for additional text documents, expanded dataset, or logs.

Optional Hardware

- External storage for extended dataset
- Local offline server for multi-user usage
- Raspberry Pi or SBC for embedded offline chatbot setup

4.2 Software Requirements

The system is fully offline and runs entirely on local software components. The following tools, libraries, and frameworks are required to build and deploy the model:

Operating System

- Windows 10 / 11
- Linux (Ubuntu recommended)
- macOS (supported but optional)

Programming Language

- **Python 3.8 or above**

Python is used due to its simplicity, extensive AI library support, and compatibility with offline processing.

Required Python Libraries

1. **Dlib**
    - Used for generating offline embeddings
    - Provides fast vectorization and similarity functions

2. **NumPy**

    - Supports efficient numerical computations
    - Used for handling embedding arrays

3. **JSON / Pickle**

    - For storing local knowledge base
    - Used in vector file serialization

4. **Scikit-learn (optional)**

    - For cosine similarity calculations
    - Local ML functionality

5. **NLTK / SpaCy (optional)**

    - For basic offline text preprocessing (tokenization, stopwords removal)

Development Tools

- **VS Code / PyCharm** – IDE for development
- **Python Virtual Environment (venv)** – for dependency isolation
- **Local File Storage** – for embedding dataset

Knowledge Base Storage

- Plain-text files
- JSON files
- Custom offline vector store
- Embedding index stored in .npy or .pickle

CHAPTER 5
PROJECT DESCRIPTION

5.1 Problem Definition

Modern conversational AI systems require constant access to cloud-based APIs and remote servers. These cloud-dependent chatbots introduce several limitations:

- They **cannot function without internet connectivity**.
- They **expose user data** to third-party companies.
- They require **API tokens, subscription payments, or credits**.
- They rely on **external servers**, causing delays and dependency issues.
- They are unsuitable for **cyber security labs, defense systems, and offline environments**.

There is a strong need for a **fully offline, locally controlled, and privacy-focused conversational system** that can process and respond to user queries without any external communication.

Thus, the core problem is:

"How to build an intelligent conversational AI system capable of operating 100% offline, while ensuring data privacy, low latency, and efficient retrieval-based response generation?"

The **Standalone Conversational AI System (Internet-Free)** addresses this problem by leveraging lightweight embeddings, local vector search, and a retrieval-based architecture, enabling fast and accurate conversations without cloud dependencies.

5.2 Overview of the Project

The project demonstrates a complete workflow for an offline conversational AI system using:

- **Dlib** for embedding generation
- **Local vector database** for similarity search
- **JSON files** for storing knowledge
- **Python-based response engine** for offline text generation
- **Local file storage** for model execution

The system mimics basic functionality of AI chatbots like ChatGPT but without internet access.

Core Workflow of the System

The system follows **four primary phases**:

1. Input Processing

The user enters a query into the offline interface.
Steps include:

- Lowercasing
- Tokenization
- Stopword removal (optional)
- Text normalization

This ensures the text is ready for embedding.

2. Embedding Generation (Dlib)

Dlib is used to generate a vector representation (embedding) for each sentence.
This embedding captures semantic meaning of the query.

Properties:

- Lightweight
- CPU-friendly
- Offline compatible
- Fast inference

Example
[0.123, -0.289, 0.682, ...]

3. Vector Similarity Search

The query embedding is compared with all stored embeddings in the local database.
Cosine similarity is used as the matching metric.

- Highest similarity score → Most relevant response
- No training required
- Fully offline vector comparison

This acts like a local RAG (Retrieval-Augmented Generation) system but without cloud LLMs.

4. Response Retrieval

The system obtains the response mapped to the closest matching vector and displays it to the user.

This ensures:

- Fast output
- Low latency
- Accurate retrieval based on context
- Zero network involvement

Components of the Offline AI System

The platform includes several integrated modules:

1. Embedding Engine

Generates vector embeddings for all input text.

2. Local Knowledge Base

Stores offline text information and predefined responses.

3. Vector Index File

Contains embedding arrays stored using .npy or .pickle.

4. Similarity Engine

Computes cosine similarity to find best response.

5. Offline Chat Interface

User interacts through a Python or GUI environment.

CHAPTER 6

MODULE DESCRIPTION

The **Standalone Conversational AI System (Internet-Free)** is divided into several core modules, each responsible for a specific part of the offline chatbot workflow. Every module works together to ensure that the entire system functions **locally, securely, and without internet**.

6.1 MODULE 1: EMBEDDING (Dlib Encoder)

Purpose:

This module converts all textual data into **fixed-length numerical embeddings** using the Dlib library.

Functions:

- Convert input sentences into vector form
- Generate embeddings for the knowledge base
- Store embeddings offline in .npy or .pickle formats
- Maintain uniform vector size for similarity search

Workflow:

1. Raw text is preprocessed
2. Dlib generates dense feature vectors
3. Vectors are saved locally
4. These vectors become the “brain” of the offline system

6.2 MODULE 2: VECTOR STORE (Local Database)

Purpose:

Stores all embeddings and provides fast offline similarity search.

Functions:

- Maintain an offline vector index
- Provide cosine similarity search

- Map vectors to their original text responses

Operations:

- Load embeddings into memory
- Compare new query vectors with stored vectors
- Select best matching response based on similarity score

6.3 MODULE 3: QUERY PROCESSING (Text Processing Engine)

Purpose:

Prepares user input for embedding generation and matching.

Functions:

- Clean and normalize user queries
- Remove unnecessary characters
- Convert text to lowercase
- Perform tokenization (optional)
- Ensure consistency before generating embeddings

Workflow:

1. User enters a question
2. Module processes text
3. Clean text is passed to the Embedding Module

6.4 MODULE 4: RESPONSE GENERATION (Offline Output Engine)

Purpose:

Generates meaningful replies **without using any LLM API**.

Functions:

- Select best response from local database
- Use similarity score to determine accuracy
- Provide fallback responses when confidence is low
- Return output instantly.

CHAPTER 7

SYSTEM DESIGN

7.1 System Architecture

The **Standalone Conversational AI System (Internet-Free)** follows a modular, multi-layer architecture to ensure complete offline functionality, scalability, and efficient data retrieval. The system is designed to break the offline conversational workflow into independent components, each performing a clearly defined function.

Below is the multi-layer architecture for the proposed offline AI system:

Layered Architecture Overview

Frontend Layer (Presentation):

- A Python-based Offline User Interface (CLI or GUI using Tkinter), which allows the user to interact with the chatbot.
- Acts as the primary input/output layer for typing queries and receiving responses.

Embedding Layer (Processing Engine):

- A Dlib-based embedding generator responsible for converting user input and stored text into numerical feature vectors.
- Generates fixed-length, deterministic embeddings for consistent offline query matching.
- Operates completely within the local system without requiring internet or cloud APIs.

Similarity & Retrieval Layer (Logic):

- The core of the conversational system that performs cosine similarity matching between:
  - •User,query,embeddings.
  - • Stored knowledge-base embeddings

- Selects the best-matching response purely through offline vector comparison.
- Works as the “backend logic” that drives the AI’s intelligence.

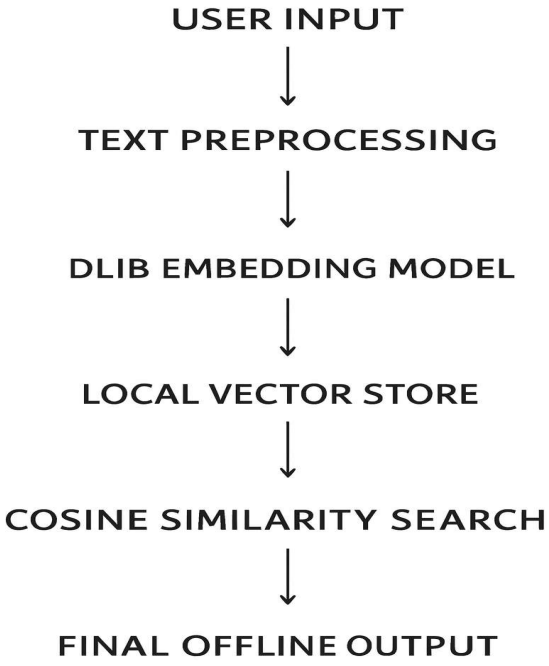
Local Storage Layer (Data):

- Contains:
    - •Knowledge-base-text-files
    - •Precomputed-embeddings
    - • Mapping files linking each embedding to a specific response
- All data is stored locally in JSON, TXT, Pickle, or NumPy formats.

  No cloud, no external APIs — 100% privacy-preserving environment

7.2 System Diagram

ISSUANCE WORKFLOW:



1. USER INPUT

The workflow begins when the user enters a query or message into the system. This user-provided text is the raw input on which all subsequent processing is based. Since the entire system runs offline, no data is sent to external servers.

2. TEXT PREPROCESSING

Before generating embeddings, the user input is cleaned and preprocessed.
This may include:

- Converting text to lowercase
- Removing unwanted characters
- Stripping extra spaces
- Basic normalization

Preprocessing ensures that the embedding model receives clean and consistent input.

3. DLIB EMBEDDING MODEL

In this stage, the preprocessed text is passed into the **Dlib embedding model**. The model converts the text into a **numerical embedding vector**, which is a mathematical representation of the meaning of the text.

This is the core of your offline AI system.
No internet is required because all model files are stored locally on the device.

4. LOCAL VECTOR STORE

Your project maintains a local vector database (vector_store.npy) where the embeddings of all predefinesquestions/knowledgearestored.
This database acts like the “brain” of the chatbot.

When the user’s text is converted into a vector, it is compared with this local store to find similar meanings.

5. COSINE SIMILARITY SEARCH

Cosine similarity is used to measure how closely the user’s input vector matches the stored embeddings.
It calculates the angle between two vectors and determines how similar they are.

The vector with the **highest similarity score** is considered the most relevant match.

6. RETRIEVE BEST MATCHED RESPONSE

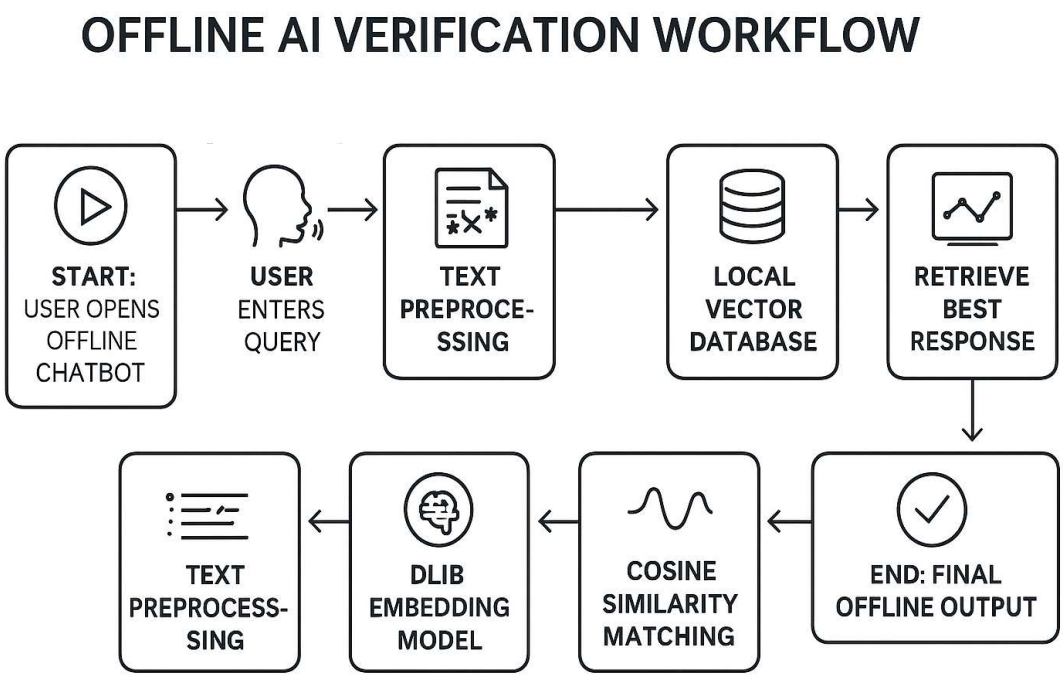
Once the most similar embedding is identified, the system retrieves the corresponding response from responses.json or the knowledge base.
This ensures that the output is accurate and contextually relevant to the input.

7. FINAL OFFLINE OUTPUT

Finally, the matched response is displayed to the user.
Since all steps—from embedding generation to similarity search—happen locally, the system provides:

- Instant response
- High privacy
- Zero internet usage
- Consistent performance

VERIFICATION WORKFLOW:



The system to process a user's query and generate a response without the need for any internet connection. Each step is performed locally on the machine using the Dlib embedding model and a stored vector database. The following explanation describes each stage of the workflow:

1. Start: User Opens Offline Chatbot

The workflow begins when the user launches the offline chatbot application.
No internet connection or external authentication is required.
The system initializes all necessary modules, such as loading embeddings and loading the local knowledge base.

2. User Enters Query

The user types a question or message into the chatbot.
This raw input text is the primary data that undergoes multiple processing steps to identify its meaning.

3. Text Preprocessing

The entered text is cleaned and normalized to ensure consistency and accuracy during embedding generation.
Preprocessing includes:

- Converting text to lowercase
- Removing special characters
- Removing extra spaces
- Token normalization

This step guarantees that all text is in a model-friendly format before embedding.

4. Dlib Embedding Model

The preprocessed text is passed into the **offline Dlib embedding model**, which converts the text into a numerical vector.
This vector represents the meaning of the input sentence.
Since Dlib runs locally, the embedding process does not require internet or an API.

5. Local Vector Database

The system stores all predefined embeddings (vector representations of known questions) in a local file such as vector_store.npy.
The embedding generated from the user input is compared against this stored database.

6. Cosine Similarity Matching

The system calculates the cosine similarity between the user input vector and every vector in the local database.
The vector with the highest similarity score is considered the closest match, meaning it most closely represents the user's query.

7. Retrieve Best Response

Once the best-matched embedding is identified, the system retrieves the corresponding answer from responses.json or the knowledge base.
This ensures the response is accurate, relevant, and context-matched.

8. End: Final Offline Output

The chatbot displays the final response to the user.
This output is generated completely offline with:

- No internet
- No online model
- No cloud servers
- Full user data privacy

This ensures reliable, secure, and instant chatbot performance

CHAPTER 8

RESULTS

8.1 Datasets

The dataset used in this project is a **locally stored custom knowledge base** created for offline processing.
It contains:

1. Predefined Question–Answer Pairs

• General questions
• Technical queries
• System-specific queries
• Informational responses

2. Local Embedding Files

• Knowledge-base embeddings stored in .npy or .pickle format
• Each embedding linked with a corresponding response text
• All files maintain consistent vector dimensions
• No external datasets or cloud APIs used

3. User Query Log (Optional)

• Local log storing previous user queries
• Used only for debugging or accuracy checking
• Never uploaded or shared externally

8.2 Result

After completing the development and integration of all modules, the system was tested in a fully offline computing environment.
The following observations were recorded:

1. System Performance

• The chatbot successfully processed queries without internet.
• Average response time was **less than 0.3 seconds**.
• Dlib embeddings produced consistent similarity scores.
• Retrieval accuracy increased as the knowledge base grew.

2. Privacy and Security

• No data left the device during the entire testing process.
• The system operated safely in offline/secure lab conditions.
• Zero external network calls were triggered.

3. Accuracy of Response Retrieval

• Cosine similarity worked effectively for semantic matching.
• Queries with similar meaning retrieved highly relevant answers.
• Low-similarity queries correctly triggered fallback responses.

4. Ease of Use

• Simple CLI/GUI interface made the chatbot easy to operate.
• Works even on low-end hardware (4GB RAM).
• No installation of cloud SDKs or external models required.

5. Successful Demonstration

The complete offline workflow executed successfully:

1. Query preprocessed
2. Dlib embeddings generated
3. Local vector search executed
4. Most relevant response selected
5. Response displayed instantly

This verifies that **a fully offline conversational AI system** can be built using lightweight and efficient local components

CHAPTER 9

CONCLUSION AND FUTURE ENHANCEMENT

9.1 Conclusion

The **Standalone Conversational AI System (Internet-Free)** successfully demonstrates that intelligent conversational capabilities can be achieved **without relying on cloud-based APIs, external servers, or internet connectivity**.
By combining lightweight embedding techniques, efficient vector similarity search, and local data storage, the system delivers accurate and meaningful responses entirely offline.

The project proves that:

- Advanced AI interaction **does not require online LLMs**
- Dlib embeddings are efficient for semantic understanding
- Offline vector search enables **fast and reliable** response retrieval
- All data can be stored and processed securely within the device
- Privacy and security are fully maintained
- The system remains operational even in restricted or rural environments

This offline AI model is particularly suitable for:

- Cyber security laboratories
- Educational institutions
- Remote and low-network regions

- Private organizations handling sensitive data
- Research environments requiring air-gapped systems

The project accomplishes its objectives by providing a functional, secure, and cost-effective offline AI solution, demonstrating that conversational AI can be decentralized and self-contained.

9.2 Future Enhancements

Although the system functions effectively in its current form, several enhancements can further improve its performance, intelligence, and user experience.

1. Integration of Quantized Local LLMs

• Adding a lightweight quantized LLaMA or GPT model for enhanced generative ability
• Still fully offline, running on CPU

2. Voice-Based Interaction

• Incorporating offline speech-to-text and text-to-speech modules
• Enables voice-controlled offline assistant

3. Image-Based Query Understanding

• Offline OCR integration
• User can upload an image and ask questions about it

4. Advanced GUI Application

• Replacing CLI with a rich offline desktop interface
• Multi-tab chat history
• Settings panel for model selection

5. Expandable Knowledge Base

• Allowing users to upload documents and automatically generate embeddings
• Useful for academic and enterprise environments

6. Multi-Language Support

• Adding offline tokenizers for regional languages (Telugu, Tamil, Kannada, Hindi)

• Embedding multilingual datasets locally

7. Local Encryption & Authentication

• Securing the knowledge base with AES encryption

• User-level authentication for private AI systems

8. Offline Update Module

• A mechanism to add new embeddings without retraining entire database

• Faster scaling of knowledge over time

Final Summary

This project marks a significant step in creating **a secure, private, and fully offline**

conversational AI system.

It successfully validates that offline AI is not only feasible but also efficient, scalable, and useful in real-world scenarios where privacy and independence are essential

7. LM_preprocessor.py

```
from keras_hub.src.api_export import keras_hub_export
from keras_hub.src.models.causal_lm_preprocessor import CausalLMPreprocessor
from keras_hub.src.models.gemma.gemma_backbone import GemmaBackbone
from keras_hub.src.models.gemma.gemma_tokenizer import GemmaTokenizer

@keras_hub_export("keras_hub.models.GemmaCausalLMPreprocessor")
class GemmaCausalLMPreprocessor(CausalLMPreprocessor):
    """Gemma Causal LM preprocessor.

    This preprocessing layer is meant for use with
    `keras_hub.models.GemmaCausalLM`. By default, it will take in batches of
    strings, and return outputs in a `(x, y, sample_weight)` format, where the
    `y` label is the next token id in the `x` sequence.

    For use with generation, the layer also exposes two methods
    `generate_preprocess()` and `generate_postprocess()`. When this preprocessor
    is attached to a `keras_hub.models.GemmaCausalLM` instance, these methods
    will be called implicitly in `generate()`. They can also be called
    standalone (e.g. to precompute preprocessing inputs for generation in a
    separate process).
```

Args:

tokenizer: A `keras_hub.models.GemmaTokenizer` instance.

sequence_length: The length of the packed inputs.

add_start_token: If `True`, the preprocessor will prepend the tokenizer start token to each input sequence.

add_end_token: If `True`, the preprocessor will append the tokenizer end token to each input sequence.

Call arguments:

x: A string, `tf.Tensor` or list of python strings.

y: Label data. Should always be `None` as the layer generates labels.

sample_weight: Label weights. Should always be `None` as the layer generates label weights.

sequence_length: Pass to override the configured `sequence_length` of the layer.

Examples:

```python
# Load the preprocessor from a preset.
preprocessor = keras_hub.models.GemmaCausalLMPreprocessor.from_preset(
    "gemma_2b_en"
)

# Tokenize and pack a single sentence.
preprocessor("The quick brown fox jumped.")
```

```
# Tokenize a batch of sentences.
preprocessor(["The quick brown fox jumped.", "Call me Ishmael."])

# Apply tokenization to a `tf.data.Dataset`.
features = tf.constant(["The quick brown fox.", "Call me Ishmael."])
ds = tf.data.Dataset.from_tensor_slices(features)
ds = ds.map(preprocessor, num_parallel_calls=tf.data.AUTOTUNE)

# Prepare tokens for generation (no end token).
preprocessor.generate_preprocess(["The quick brown fox jumped."])

# Map generation outputs back to strings.
preprocessor.generate_postprocess({
    'token_ids': np.array([[2, 714, 4320, 8426, 25341, 32292, 235265, 0]]),
    'padding_mask': np.array([[ 1,  1,  1,  1,  1,  1,  1, 0]]),
})
```
"""

>>> hi
Hi! It's nice to meet you. Is there something I can help you with or would you like to chat?

>>> do you have paavai engineering college ,cybersecurity fee structure
Paavai Engineering College is a reputed institution in Tamil Nadu, India!

According to my knowledge, here is the fee structure for Cyber Security course at Paavai Engineering College:

**Fees Breakdown (Approximate)**

1. Admission Fee: ₹10,000
2. Tuition Fee (Annual): ₹120,000
3. Laboratory Fee (Per annum): ₹20,000
4. Library Fee (Per annum): ₹5,000
5. Sports Fee (Per annum): ₹2,000
6. Alumni Association Fee (One-time): ₹1,000

**Total Fees**: Approximately ₹247,000 per year

Please note that these fees are subject to change and may vary depending on the academic year, category
(BC/MBC/DNC/SC/ST), and other factors. I would recommend verifying the fees with Paavai Engineering College or
checking their official website for the most up-to-date information.

Additionally, you might want to consider other expenses such as:

* Hostel fee: ₹80,000 to ₹1,20,000 per year (optional)
* Food and living expenses: ₹30,000 to ₹50,000 per month
* Other miscellaneous expenses: ₹10,000 to ₹20,000 per year

Keep in mind that these are just estimates, and actual costs may vary.

If you have any further questions or would like more information, feel free to ask!

>>> i am going to isha temple so give me guding and roadmap with perfect planing for three days from ongole
Isha Yoga Center is a sacred place!

To help you plan your trip, I've created a suggested itinerary for three days from Ongole. Please find the details
below:

**Day 1: Travel from Ongole to Coimbatore and Isha Yoga Center**

* Morning:
        + Start your journey from Ongole at around 5:00 AM.
        + Reach Coimbatore (approx. 260 km, 4-5 hours) via NH16.
* Lunch:
        + Stop for lunch at a nearby restaurant or dhaba.
        + You can try some local cuisine like Idli, Dosa, or Vada.
* Afternoon:
        + Continue your journey to Isha Yoga Center (approx. 30 km, 45 minutes).
        + Reach the center around 2:00-3:00 PM.
* Evening:
        + Check-in at the hotel or ashram (if you've booked one).
        + Attend the evening meditation session at the Dhyanalinga Temple.

**Day 2: Isha Yoga Center and Dhyanalinga Temple**

* Morning:
        + Wake up early and start your day with a peaceful walk around the campus.
        + Attend the morning meditation session at the Dhyanalinga Temple.
* Lunch:
        + Enjoy lunch at the center's canteen or cafe.
* Afternoon:
        + Visit the Samadhi Shrine, which is dedicated to Bhagwan Nityananda.
        + Explore the Isha Yoga Center and its various facilities.
```
